

C L A I M S :

1. An apparatus for fastening a constructional element (1) to a spectacle lens (2) with a butt end (8) of a constructional element (1) which overlaps the lens edge, with two parallel fastening pins (4) which project from the butt end (8) and form annular enlargements (5) which are barb-like in their cross section, and with plastic sleeves (6) which can be inserted into bores in the spectacle lens (2) and form a head overlapping the edge of the bore and in which the fastening pins (4) engage in an interlocking way under deformation of the sleeve wall from the side of the bore opposite of the heads, characterized in that the butt end (8) with the two fastening pins (4) is made of plastic, that the two plastic sleeves (6) are mutually connected via a joint stop head (7) and that the modulus of elasticity of the plastic of the fastening pins (4) corresponds to at least three times the modulus of elasticity of the plastic of the plastic sleeves (6).
2. An apparatus as claimed in claim 1, characterized in that the two plastic sleeves (6) consist of a crystalline plastic material and the fastening pins (4) consist of an amorphous plastic material.
